The implementation, described below, allows for fixed effects and for large clusters. Example:

2 Methods

This section describes the implementation of the Imbens and Kolesár [2016] and Bell and McCaffrey [2002] degrees of freedom adjustments.

There are S clusters, and we observe n_s observations in cluster s, for a total of $n = \sum_{s=1}^{S} n_s$ observations. We handle the case with independent observations by letting each observation be in its own cluster, with S = n. Consider the linear regression of a scalar outcome Y_i onto a p-vector of regressors X_i ,

$$Y_i = X_i'\beta + u_i, \qquad E[u_i \mid X_i] = 0.$$

We're interested in inference on $\ell'\beta$ for some fixed vector $\ell \in \mathbb{R}^p$. Let X, u, and Y denote the design matrix, and error and outcome vectors, respectively. For any $n \times k$ matrix M, let M_s denote the $n_s \times k$ block corresponding to cluster s, so that, for instance, Y_s corresponds to the outcome vector in cluster s. For a positive semi-definite matrix M, let $M^{1/2}$ be a matrix satisfying $M^{1/2}M^{1/2} = M$, such as its symmetric square root or its Cholesky decomposition.

Assume that

$$E[u_s u_s' \mid X] = \Omega_s$$
, and $E[u_s u_t' \mid X] = 0$ if $s \neq t$.

Denote the conditional variance matrix of u by Ω , so that Ω_s is the block of Ω corresponding to cluster s. We estimate $\ell'\beta$ using OLS. In R, the OLS estimator is computed via a QR decomposition, X = QR, where Q'Q = I and R is upper-triangular, so we can write the estimator as

$$\ell'\hat{\beta} = \ell'\left(\sum_s X_s'X_s\right)^{-1} \sum_s X_sY_s = \tilde{\ell}'\sum_s Q_s'Y_s, \qquad \tilde{\ell} = R^{-1'}\ell.$$

It has variance

$$V := \operatorname{var}(\ell'\hat{\beta} \mid X) = \ell' \left(X'X \right)^{-1} \sum_{s} X'_{s} \Omega_{s} X_{s} \left(X'X \right)^{-1} \ell = \tilde{\ell}' \sum_{s} Q'_{s} \Omega_{s} Q_{s} \tilde{\ell}.$$

2.1 Variance estimate

We estimate *V* using a variance estimator that generalizes the HC2 variance estimator to clustering. Relative to the LZ2 estimator described in Imbens and Kolesár [2016], we use a slight modification that allows for fixed effects:

$$\hat{V} = \ell'(X'X)^{-1} \sum_{s} X'_{s} A_{s} \hat{u}_{s} \hat{u}'_{s} A'_{s} X_{s} (X'X)^{-1} \ell = \ell' R^{-1} \sum_{s} Q'_{s} A_{s} \hat{u}_{s} \hat{u}'_{s} A'_{s} Q_{s} R'^{-1} \ell = \sum_{s=1}^{S} (\hat{u}'_{s} a_{s})^{2},$$

where

$$\hat{u}_s := Y_s - X_s \hat{\beta} = u_s - Q_s Q' u, \qquad a_s = A_s' Q_s \tilde{\ell},$$

and the matrix A_s is given by the symmetric square root of the inverse of $I - Q_s Q_s'$, or else its pseudo-inverse if it is singular, as is the case, for example, if X contains fixed effects. We do not need to insist on $I - Q_s Q_s'$ to be invertible, since, using the identity

$$\hat{V} = u \sum_{s} (I - QQ')'_{s} a_{s} a'_{s} (I - QQ')_{s} u,$$

one can verify by simple algebra that a sufficient condition for \hat{V} to be unbiased under homoskedasticity is that $Q'_s A_s (I - Q_s Q'_s) A_s Q_s = Q'_s Q_s$ (see, for example, Pustejovsky and Tipton [2018], for details).

If the observations are independent, the vector of leverages $(Q_1'Q_1,\ldots,Q_n'Q_n)$ can be computed directly using the stats::hatvalues function. In this case, use this function to compute $A_i = 1/\sqrt{1 - Q_i'Q_i}$ directly, and we then compute $a_i = A_iQ_i'\tilde{\ell}$ using vector operations. For the case with clustering, computing the spectral decomposition of $I - Q_sQ_s'$ can be expensive or even infeasible if the cluster size n_s is large. We therefore use the following result, suggested to us by Ulrich Müller, allows us to compute a_s by computing a spectral decomposition of a $p \times p$ matrix.

• Let $Q_s'Q_s = \sum_{i=1}^p \lambda_{is}r_{is}r_{is}'$ be the spectral decomposition of $Q_s'Q_s$. Then $A_s = \sum_{i: \lambda_i \neq 1} (1 - \lambda_i)^{-1/2}Q_sr_{is}r_{is}'C_{s}'$ satisfies $A_s(I - Q_sQ_s')A_s = I$.

This follows from the fact that $I - Q_s Q_s'$ has eigenvalues $1 - \lambda_{is}$ and eigenvectors $Q_s r_{is}$, and

hence its pseudoinverse is $\sum_{i: \lambda_i \neq 1} (1 - \lambda_i)^{-1} Q_s r_{is} r'_{is} Q'_s$.

Using the lemma, we can compute a_s efficiently as:

$$a_s = \sum_{i: \lambda_i \neq 1} (1 - \lambda_i)^{-1/2} Q_s r_{is} r'_{is} Q'_s Q_s \tilde{\ell} = Q_s D_s \tilde{\ell}, \qquad D_s = \sum_{i: \lambda_i \neq 1} \lambda_i (1 - \lambda_i)^{-1/2} r_{is} r'_{is}.$$

2.2 Degrees of freedom correction

Let *G* be an $n \times S$ matrix with columns $(I - QQ')'_s a_s$. Then the Bell and McCaffrey [2002] adjustment sets the degrees of freedom to

$$f_{\rm BM} = \frac{\operatorname{tr}(G'G)^2}{\operatorname{tr}((G'G)^2)}.$$

Since $(G'G)_{st} = a'_s(I - QQ')_s(I - QQ)'_t a_t = a_s(\mathbb{1}\{s = t\} - Q_sQ'_t)a_t$, the matrix G'G can be efficiently computed as

$$G'G = \operatorname{diag}(a'_s a_s) - BB'$$
 $B_{sk} = a'_s Q_{sk}$.

Note that *B* is an $S \times p$ matrix, so that computing the degrees of freedom adjustment only involves $p \times p$ matrices:

$$f_{\text{BM}} = \frac{(\sum_{s} a'_{s} a_{s} - \sum_{s,k} B^{2}_{sk})^{2}}{\sum_{s} (a'_{s} a_{s})^{2} - 2\sum_{s,k} (a'_{s} a_{s}) B^{2}_{sk} + \sum_{s,t} (B'_{s} B_{t})^{2}}.$$

If the observations are independent, we compute B directly as B <- a*Q, and since a_i is a scalar, we have

$$f_{\text{BM}} = \frac{(\sum_{i} a_i^2 - \sum_{sk} B_{sk}^2)^2}{\sum_{i} a_i^4 - 2\sum_{i} a_i^2 B_i' B_i + \sum_{i,j} (B_i' B_j)^2}.$$

The Imbens and Kolesár [2016] degrees of freedom adjustment instead sets

$$f_{IK} = \frac{\operatorname{tr}(G'\hat{\Omega}G)^2}{\operatorname{tr}((G'\hat{\Omega}G)^2)},$$

where $\hat{\Omega}$ is an estimate of the Moulton [1986] model of the covariance matrix, under which $\Omega_s = \sigma_\epsilon^2 I_{n_s} + \rho \iota_{n_s} \iota'_{n_s}$. Using simple algebra, one can show that in this case,

$$G'\Omega G = \sigma_{\epsilon}^2 \operatorname{diag}(a_s'a_s) - \sigma_{\epsilon}^2 BB' + \rho(D - BF')(D - BF')',$$

where

$$F_{sk} = \iota'_{n_s} Q_{sk}, \qquad D = \operatorname{diag}(a'_s \iota_{n_s})$$

which can again be computed even if the clusters are large. The estimate $\hat{\Omega}$ replaces σ_{ϵ}^2 and ρ with analog estimates.
